1 SUPRANE (100% inhalation, volatile liquid)

Suprane, 100%, volatile liquid for inhalation.

2 QUALITATIVE AND QUANTITATIVE COMPOSITION

Desflurane 100% (USP) (1g/g).

3 PHARMACEUTICAL FORM

Volatile liquid for inhalation.

Desflurane is a colourless, mobile liquid, practically odourless and tasteless at below 23°C.

4 CLINICAL PARTICULARS

4.1 Therapeutic indications

Suprane is indicated as an inhalation agent for induction and maintenance of anaesthesia in adults and maintenance of anaesthesia in infants and children. **Suprane** is not recommended for induction of anaesthesia in paediatric patients.

4.2 Dose and method of administration

Suprane is administered by inhalation. The concentration of **Suprane** should be administered by persons trained in the administration of general anaesthesia and delivered from a vaporiser specifically designed and designated for use with **Suprane** (see section 4.4).

The vapour pressure of **Suprane** at room temperature (about 700mm Hg) precludes its use in commonly-used agent-specific vaporisers as such vaporisers cannot provide a stable and predictable delivered concentration. Unlike agent-specific vaporisers, **Suprane** requires a vaporiser which utilises a heated sump (enclosure containing liquid desflurane) to prevent condensation, which could occur should the temperature in the sump fall below 22.8°C at 1 atmosphere pressure (desflurane boiling point). To power the heating elements, the vaporiser must be connected to an electrical source. A vaporiser designed for use with **Suprane** must also include a filling port compatible with the valve on the **Suprane** bottle.

Premedication

The premedication should be chosen to suit the individual requirements of the patient. Studies to date with patients scheduled to be anaesthetized have frequently received IV premedication such as opioids and/or benzodiazepines, and these have not shown an effect of premedication on respiratory tract reactions associated with inhalational induction of anaesthesia.

Dosage

The minimum alveolar concentration (MAC) of **Suprane** is age-specific and decreases with increasing patient age. The administration of general anaesthesia must be individualised based on the patient's response, thus the dose of **Suprane** should be adjusted accordingly individually. The MAC has been determined as listed in the table below (see section 5.1):

Effect of Age on Suprane MAC		
Age100% oxygen60% nitrous oxide/ (end-tidal %)40% oxygen (end-tidal %)		
0 - 1 Year	8.95 - 10.65	5.75 - 7.75*
1 - 12 Years	7.20 - 9.40	5.75 - 7.00**
18 - 30 Years	6.35 - 7.25	3.75 - 4.25
30 - 65 Years	5.75 - 6.25	1.75 - 3.25
Over 65 Years	5.17 ± 0.6	1.67 ± 0.4
* 3 - 12 months ** 1 - 5 Years	•	·

The MAC for desflurane is reduced by concomitant N₂O administration.

Opioids or benzodiazepines decrease the amounts of **Suprane** required to produce anaesthesia. **Suprane** decreases the doses of neuromuscular blocking agents (see section 4.5).

In patients with coronary artery disease, maintenance of normal haemodynamics is important to avoid myocardial ischaemia. **Suprane** should not be used as the <u>sole</u> anaesthetic in patients with coronary artery disease or in patients where increases in heart rate or blood pressure are undesirable. Thus, when **Suprane** is to be used in patients with coronary artery disease, it should always be used in combination with other medicines, such as intravenous opioids or hypnotics and it should not be used for induction (see section 4.4).

Induction of anaesthesia

Suprane is not recommended for induction of general anaesthesia (see sections 4.3 and 4.4) via mask because of the high incidence of upper airway adverse events such as laryngospasm, apnoea, increase in secretions, breath-holding and coughing, especially in children and infants with high concentrations of **Suprane**.

After induction in adults with an intravenous medicine such as thiopental or propofol, **Suprane** can be started at approximately 0.5 to 1 MAC, whether the carrier gas is O_2 or N_2O/O_2 .

In patients with known or suspected increases in cerebrospinal fluid pressure, desflurane should be administered at 0.8 MAC or less in conjunction with a barbiturate or propofol induction and hyperventilation (hypocapnia) in the period before cranial decompression. Appropriate attention must be paid to maintain cerebral perfusion pressure (see sections 5.1 Clinical efficacy and safety/Neurosurgery and 4.4).

Maintenance of anaesthesia

Surgical levels of anaesthesia may be sustained with 2 to 6% end-tidal concentration of **Suprane** when N_2O is used concomitantly. **Suprane** at 2.5 to 8.5% end-tidal concentration may be required when administered using O_2 or oxygen enriched air.

In children, surgical levels of anaesthesia may be maintained with end-tidal concentrations of 5.2 to 10% **Suprane** with or without the concomitant use of N₂O. Although end-tidal concentrations of up to 18% desflurane have been administered for short periods of time, if high concentrations are used with N₂O, it is important to ensure that the inspired mixture contains a minimum of 25% O₂.

Blood pressure and heart rate should be monitored carefully during maintenance as part of the evaluation of depth of anaesthesia.

If added relaxation is required, supplemental doses of muscle relaxants may be used.

Dosage in renal and hepatic impairment

End-tidal concentrations of 1 to 4% in N_2O/O_2 have been used in patients with chronic renal or hepatic impairment and during renal transplantation surgery. Because of minimal metabolism, a need for dose adjustment in patients with renal and hepatic impairment is not to be expected.

4.3 Contraindications

Suprane is contraindicated in those patients:

- in whom general anaesthesia is contraindicated
- with known sensitivity to halogenated agents and in patients with known or genetic susceptibility to malignant hyperthermia
- with a history of malignant hyperthermia, or in whom liver dysfunction, hepatitis or jaundice with unexplained fever, leucocytosis, and/or eosinophillia has occurred after a previous halogenated anaesthetic administration
- paediatric patients, as an inhalation induction agent, because of the frequent occurrence of cough, breath-holding, apnoea, laryngospasm and increased secretions.

4.4 Special warnings and precautions for use

Suprane should only be administered by persons trained in the administration of general anaesthesia using a vaporiser specifically designed and designated for use with **Suprane**. Facilities for maintenance of a patent airway, artificial ventilation, oxygen enrichment and circulatory resuscitation must be immediately available. Hypotension and respiratory depression increase as anaesthesia is deepened.

Suprane is not recommended for use as an inhalation induction agent in adults, children and infants (see section 4.3) because of the frequent occurrence of cough, breath-holding, apnoea, laryngospasm and increased secretions.

Desflurane, as with other halogenated anaesthetics, has been reported to interact with dry carbon dioxide (CO₂) absorbents to form carbon monoxide that may result in elevated levels of carboxyhemoglobin in some patients. Case reports suggest that barium hydroxide lime and soda lime become desiccated when fresh gases are passed through the CO₂ absorber canister at high flow rates over many hours or days, or after the machine has been idle for two or more days. An *ex vivo* study suggests that barium hydroxide lime has greater potential for carbon monoxide production but the phenomenon may also occur with dried soda lime when fresh gases are passed through the CO₂ canister at high flow rate over many hours or days. In order to minimise the risk of formation of carbon monoxide in rebreathing circuits and the possibility of elevated carboxyhaemoglobin levels, fresh (moist) CO₂ absorbents should be used. The moisture content of soda lime should always be $\geq 5\%$ water, and that of Baralyme, $\geq 10\%$ water. When the anaesthetist has any doubt regarding the moisture content of the CO₂ absorbent, or suspects that the CO₂ absorbent may be desiccated, it should be replaced before administration of desflurane.

In addition, consideration should be given to direct measurement of carboxyhaemoglobin levels in patients on closed circuit anaesthesia with desflurane, if oxygen desaturation develops which does not respond to usual corrective steps.

Fluoroform is another degradation product. Adequate data on the toxicology of fluoroform are not available.

As with other rapid-acting anaesthetic agents, rapid emergence with desflurane should be taken into account in cases where post-anaesthesia pain is anticipated. Care should be taken that appropriate analgesia has been administered to the patient at the end of the procedure or early in the post-anaesthesia care unit stay.

There is insufficient experience of use in repeated anaesthesia to make a definite recommendation in this regard. As with all halogenated anaesthetics, repeat anaesthesia within a short period of time should be approached with caution.

In healthy volunteers, in the absence of concomitant N₂O and/or opioid administration, sudden step increases in the inspired concentration of desflurane may cause transient increases in sympathetic activity with associated increases in heart rate and blood pressure. The haemodynamic changes are more common at concentrations \geq 6% and more severe with large (\geq 1%), sudden increments. Without treatment, and without further increases in desflurane concentration, these increases in heart rate and blood pressure resolve in approximately 4 minutes. At the new, higher inspired desflurane concentration blood pressure is likely to be lower and heart rate higher than at the previous, lower steady-state desflurane concentration of desflurane is increases of heart rate and blood pressure are less if the inspired concentration of desflurane is increased in increments of 1% or less. However, if during the transiently increased heart rate and blood pressure end-tidal concentration of desflurane is again increased, further increase of heart rate and blood pressure may result. Administration of sympatholytic medicines (fentanyl, alfentanil, esmolol, clonidine) prior to a sudden step increase of desflurane blunts or blocks the increase in heart rate and blood pressure. The sympathetic response is not obtunded by intravenous or endotracheal lignocaine or by intravenous propofol.

During maintenance of anaesthesia, increases in heart rate and blood pressure occurring after rapid incremental increases in end-tidal concentration of desflurane may not represent inadequate anaesthesia. The changes due to sympathetic activation resolve in approximately 4 minutes. Increases in heart rate and blood pressure occurring before or in the absence of a rapid increase in desflurane concentration may be interpreted as light anaesthesia. Thus, in such patients, incremental increases of 0.5 - 1.0% end-tidal desflurane may attenuate these signs of light anaesthesia, as may concomitant administration of analgesics. Should raised heart rate and blood pressure persist, then other causes should be sought.

Hypotension and respiratory depression increase as anaesthesia is deepened.

When changing the depth of anaesthesia, rapid increases in the end-tidal concentration of desflurane should be avoided and the end-tidal concentration increased in small amounts of 1% or less. It is not necessary to deliver concentrations of desflurane far in excess of the desired end-tidal concentration ("overpressurisation" technique) due to the low blood and tissue solubilities of desflurane and the resulting rapid equilibrium of alveolar concentration with inspired and delivered concentrations; thus the transient and self-limiting increases in heart rate and blood pressure may be avoided.

In patients with coronary artery disease, maintenance of normal hemodynamics is important to avoid myocardial ischemia. Desflurane should not be used as the <u>sole</u> anaesthetic in patients with coronary artery disease or in patients where increases in heart rate or blood pressure are undesirable. Rapid inhaled induction of anaesthesia with desflurane alone, without concomitant administration of an opioid, in patients with coronary artery disease, has been associated with an

increased incidence of myocardial ischaemia marked increases in pulse rate, increases in mean arterial pressure and increases in adrenaline and noradrenaline levels. Desflurane, when given in conjunction with opioids for maintenance of anaesthesia in patients with coronary artery disease, has not produced an incidence of ischaemia different from that produced by other anaesthetics. Thus, when desflurane is to be used in patients with coronary artery disease, it should always be used in combination with other medicaments, such as intravenous opioids or hypnotics and it should not be used for induction.

Desflurane, as with other volatile anaesthetics, may produce a dose-dependent increase in cerebrospinal fluid (CSF) or intracranial pressure in patients with space occupying lesions. In such patients, desflurane should be administered at 0.8 Minimum Alveolar Concentration (MAC) or less, and in conjunction with a barbiturate or propofol induction and hyperventilation (hypocapnia) in the period before cranial decompression. Appropriate attention must be paid to maintain cerebral perfusion pressure.

Use of desflurane in hypovolaemic, hypotensive and debilitated patients has not been extensively investigated. As with other potent inhaled anaesthetics, a lower concentration is recommended for use in these patients.

As with other agents of this type, desflurane was shown to be a potential trigger of a skeletal muscle hypermetabolic state leading to high oxygen demand and the clinical syndrome known as malignant hyperthermia (MH). The syndrome includes non-specific features such as hypercapnia, muscle rigidity, tachycardia, tachypnoea, cyanosis, arrhythmias and/or unstable blood pressure and an increase in overall metabolism may be reflected in an elevated temperature. Some of these non-specific signs may also appear during light anaesthesia: acute hypoxia, hypercapnia and hypervolaemia. If malignant hyperthermia occurs, discontinue triggering agent(s). Administration of intravenous dantrolene sodium will be indicated to reverse this hyperthermia, as well as application of supportive therapy. Desflurane should not be used in subjects known to be susceptible to MH (see sections 4.3 and 4.8). Renal failure may appear later, and urine flow should be monitored and sustained if possible. Fatal outcome of malignant hyperthermia has been reported with desflurane.

Due to limited experience in obstetric operations, including termination of pregnancy, desflurane cannot be recommended for this type of surgery. Desflurane is a uterine-relaxant and reduces the uterine-placental blood-flow (see section 4.6 Pregnancy).

Desflurane should not be used in patients in whom liver dysfunction, unexplained fever or leucocytosis has occurred after a previous halogenated anaesthetic administration. With the use of halogenated anaesthetics, disruption of the liver function, jauncide and fatal liver necrosis have been reported. Such reactions appear to indicate hypersensitivity reactions to anaesthetics. Desflurane may cause sensitivity hepatitis in patients who have been sensitised by previous exposure to halogenated anaesthetics. Cirrhosis, viral hepatitis, or other pre-existing liver disease can be a reason to select an anaesthetic other than a halogenated anaesthetic.

As with other halogenated anaesthestics agents, desflurane has been associated with some elevation of glucose intra-operatively.

Use of inhaled anaesthetic agents, including desflurane, has been associated with rare increases in serum potassium levels that have resulted in cardiac arrhythmias, some fatal, in patients during the postoperative period. Patients with latent as well as overt muscular dystrophies, particularly Duchenne Muscular Dystrophy, appear to be most vulnerable. Concomitant use of succinylcholine has been associated with most, but not all, of these cases. These patients also experienced significant elevations in serum creatinine kinase levels and, in some cases, changes in urine

consistent with myoglobinuria. Despite the similarity in presentation to malignant hyperthermia, none of these patients exhibited signs or symptoms of muscle rigidity or hypermetabolic state. Early and aggressive intervention to treat the hyperkalaemia and resistant arrhythmias is recommended, as is subsequent evaluation for latent neuromuscular disease.

Use in the elderly

The minimum alveolar concentration (MAC) of SUPRANE is age-specific and decreases with increasing patient age. The administration of general anaesthesia must be individualised based on the patient's response, thus the dose of desflurane should be adjusted accordingly individually. See table in section 4.2.

Paediatric use

Suprane is not approved for maintenance of anaesthesia in non-intubated children under the age of 6 years due to an increased incidence of respiratory adverse reactions. Caution should be exercised when desflurane is used for maintenance anaesthesia with laryngeal mask airway (LMA) in children 6 years old or younger because of the increased potential for adverse respiratory events, e.g. coughing and laryngospasm, especially with removal of the LMA under deep anaesthesia.

Suprane should be used with caution in children with asthma or a history of recent upper airway infection due to the potential for airway narrowing and increases in airway resistance.

Emergence from anaesthesia in children may evoke a brief state of agitation that may hinder cooperation.

Paediatric Neurotoxicity

Some published studies in children have observed cognitive deficits after repeated or prolonged exposures to anaesthetic agents early in life. These studies have substantial limitations, and it is not clear if the observed effects are due to the anaesthetic/analgesic/sedation drug administration or other factors such as the surgery or underlying illness.

Published animal studies of some anaesthetic/analgesic/sedation drugs have reported adverse effects on brain development in early life and late pregnancy. The clinical significance of these nonclinical finding is yet to be determined

With inhalation or infusion of such drugs, exposure is longer than the period of inhalation or infusion. Depending on the drug and patient characteristics, as well as dosage, the elimination phase may be prolonged relative to the period of administration.

QT Prolongation

QT prolongation, very rarely associated with torsade de pointes, has been reported (see section 4.8). Caution should be exercised when administering desflurane to susceptible patients.

Effects on laboratory tests

The effect of this medicine on laboratory tests has not been established.

4.5 Interaction with other medicines and other forms of interaction

No clinically significant adverse interactions with commonly used pre-anaesthetic medicines, or medicines used during anaesthesia (muscle relaxants, intravenous agents, and local anaesthetic agents) were reported in clinical trials. The effect of desflurane on the disposition of other medicines has not been determined.

Non-depolarising and depolarising muscle relaxants

Commonly used muscle relaxants are potentiated by desflurane. Anaesthetic concentrations of desflurane at equilibrium reduce the ED_{95} of succinylcholine by approximately 30% and that of atracurium and pancuronium by approximately 50% compared to N₂O/opioid anaesthesia. The doses of pancuronium, atracurium, suxamethonium and vecuronium needed to produce 95% (ED_{95}) depression in neuromuscular transmission at different concentrations of **Suprane** are given in the following table. With the exception of vecuronium, these doses are similar to isoflurane. The ED_{95} of vecuronium is 14% lower with desflurane than isoflurane. Additionally, recovery from neuromuscular blockade is longer with desflurane than with isoflurane.

Dosage of Muscle Relaxant Causing 95% Depression in Neuromuscular Transmission at Common Suprane Concentrations				
Suprane Concentration	Mean ED95 (mg/kg)			
	Pancuronium	Atracurium	Suxamethonium	Vecuronium
0.65 MAC/60% N2O/O2	0.026	0.133	*NA	*NA
1.25 MAC/60% N ₂ O/O ₂	0.018	0.119	*NA	*NA
1.25 MAC/100% O2	0.022	0.120	0.360	0.019
* NA = Not Available MAC=Minimum Alveolar Concentration				

Opioids and benzodiazepines

Lower doses of desflurane are required in patients receiving opioids, benzodiazepines or other sedatives. These interactions are illustrated below. In addition, concomitant nitrous oxide reduces desflurane MAC, as illustrated under dosage, below. Patients anaesthetised with different concentrations of desflurane who received increasing doses of intravenous fentanyl or intravenous midazolam showed a marked reduction in the anaesthetic requirements or MAC. The administration of increasing doses of intravenous midazolam showed a small reduction in MAC. Results are reported in the following table. These MAC reductions are similar to those observed with isoflurane. It is anticipated that there will be a similar influence on MAC with other opioid and sedative medicines.

Effect of Fentanyl or Midazolam on Suprane MAC		
	*MAC (end-tidal %)	% MAC reduction
No Fentanyl	6.33 - 6.35	-
Fentanyl (3µg/kg)	3.12 - 3.46	46 - 51
Fentanyl (6µg/kg)	2.25 - 2.97	53 - 64
No Midazolam	5.85 - 6.86	-
Midazolam (25µg/kg)	4.93	15.7
Midazolam (50µg/kg)	4.88	16.6
* Includes value for ages 18 - 65 y	ears	

Concentration of other gases

The MAC for desflurane is reduced by concomitant N₂O administration (see section 4.2).

Glucose elevation

As with other halogenated anaesthestics agents, desflurane has been associated with some elevation of glucose intra-operatively (see section 4.4).

See section 6.2

4.6 Fertility, pregnancy and lactation

Effects on fertility

Studies in rats showed a slight reduction in male fertility and pregnancy rates after exposure to desflurane at exposures producing parental toxicity (mortalities and reduced weight gain). Fertility was not affected after 1 MAC hour per day desflurane exposure (cumulative 63 and 14 MAC hours for males and females respectively).

Pregnancy (Category B3)

No teratogenic effect was observed in rats or rabbits at approximately 40 cumulative MAC hour desflurane exposures during organogenesis. At this cumulative anaesthetic exposure an increase in foetal death (post-implantation loss) was observed in rats but not rabbits. These effects were observed at exposures producing a significant reduction in maternal body weight gain.

No studies of peri/post-natal physical and functional development following maternal exposures to desflurane have been conducted in animals, but a limited study in rats showed offspring body weight to be reduced by 12 - 18% over the lactation period (day 0 - 21 post-partum) following maternal exposure to 1 MAC desflurane for 4h/day from day 15 of gestation to day 21 of lactation.

Published animal studies of some anaesthetic/analgesic/sedation drugs have reported adverse effects on brain development in early life and late pregnancy.

In published foetal rhesus macaque studies, isoflurane exposed in utero resulted in increased neuronal and oligodendrocyte apoptosis in developing brain of the offspring. Studies in juvenile animals suggest neuroapoptosis correlates with long-term cognitive deficits.

Published studies in pregnant and juvenile animals demonstrate that the use of anaesthetic/ analgesic and sedation drugs that block NMDA receptors and/or potentiate GABA activity during the period of rapid brain growth or synaptogenesis may result in neuronal and oligodendrocyte cell loss in the developing brain and alterations in synaptic morphology and neurogenesis when used for longer than 3 hours. These studies included anaesthetic agents from a variety of drug classes.

There are no adequate and well-controlled studies in pregnant women. As desflurane is a uterine relaxant and reduces the uterine-placental blood flow, and safety has not been established for use in obstetric procedures, **Suprane** should be used during pregnancy only if the potential benefit justifies the potential risk to the foetus.

Breast-feeding

There are no adequate data in lactating women. **Suprane** is not indicated for use in nursing mothers because it is not known whether it is excreted in human milk.

4.7 Effects on ability to drive and use machines

There is no information of the effects of **Suprane** on the ability to drive or operate machinery. However, patients should be advised that the ability to perform tasks such as driving or operation of machinery may be impaired after general anaesthesia, and it is advisable to avoid such tasks for a period of 24 hours.

4.8 Undesirable effects

As with all potent inhaled anaesthetics, **Suprane** may cause dose-dependent hypotension. A dose-dependent respiratory depression is also observed. Most other adverse events are mild and transient.

Desflurane is not recommended for use as an inhalational induction agent because of the frequent occurrence of cough, breath-holding, apnoea, laryngospasm and increased secretions.

Nausea and vomiting have been observed in the postoperative period, common sequelae of surgery and general anaesthesia, which may be due to inhalational anaesthetic, other agents administered intraoperatively or post-operatively and to the patient's response to the surgical procedure.

Adverse event information is derived from controlled clinical trials. The studies were conducted using a variety of premedications, other anaesthetics, and surgical procedures of varying length. Of the 1,843 patients exposed to **Suprane** in clinical trials, 1,209 were used in estimating the incidence of common adverse reactions (> 1% occurrence) below, 370 adults and 152 children in whom anaesthesia was induced with **Suprane** alone and 687 patients in whom anaesthesia was maintained principally with **Suprane**. Frequencies reflect the percent of patients with the event and each patient was counted once for each type of adverse event. They are presented in alphabetical order within each body system.

Post marketing adverse reactions

In addition to the adverse reactions noted in clinical trials, the following adverse reactions have been reported in the post-marketing experience.

Blood and lymphatic system disorders Coagulopathy

Metabolism and nutrition disorders Hyperkalaemia, Hypokalaemia, Metabolic acidosis

Nervous system disorders Convulsion, Dizziness, Migraine

Eye disorders Ocular icteris

Cardiac disorders Cardiac arrest, Torsade de pointes, Ventricular failure, Ventricular hypokinesia, Atrial fibrillation

Vascular disorders Malignant hypertension, Haemorrhage, Hypotension, Shock

Respiratory, thoracic and mediastinal disorders

Respiratory arrest, Larynogospasm, Respiratory failure, Hypoxia, Respiratory distress, Bronchospasm, Haemoptysis

Gastrointestinal disorders Pancreatitis acute, Abdominal pain

Hepatobiliary disorders Hepatic failure, Hepatic necrosis, Hepatitis¹, Cytolytic hepatitis, Cholestasis, Jaundice, Hepatic function abnormal, Liver disorder

Skin and subcutaneous tissue disorder Urticaria, Erythema

Musculoskeletal, connective tissue, and bone disorders **Rhabdomyolysis**

General disorders and administration site conditions **Hyperthermia malignant, Asthenia, Malaise**

Investigations

Electrocardiogram ST-T change, Electrocardiogram T wave inversion, Transaminases increased, Alanine aminotransferase increased, Aspartate aminotransferase increased, Blood bilirubin increased, Coagulation test abnormal, Ammonia increased

Injury, poisoning and procedural complications*

Dizziness, Migraine, Tachyarrhythmia, Palpitations, Eye burns, Blindness transient, Encephalopathy, Ulerative keratitis, Ocular hyperaemia, Visual acuity reduced, Eye irritation, Eye pain, Fatigue, Accidental exposure, Skin burning sensation, Drug administration error

* All of the reactions categorised within this SOC were accidental exposure to non-patients.

Other adverse reactions reported with similar products include: Cardiac disorders Electrocardiogram QT prolonged.

Laboratory findings

Transient elevations in glucose and white blood cell count may occur as with the use of other anaesthetic agents. Abnormal liver function tests were observed in < 1% of patients.

Hepatitis has been reported very rarely < 0.0001%¹.

A comparison of the adverse events most frequently reported for desflurane and its main comparator in the controlled clinical trials, isoflurane, can be found in the following table. With the exception of respiratory complications (primarily occurring during the induction period), adverse event rates are comparable.

Comparison of Adverse	Events: desflurane and isoflur	ane
(most frequently reported events)		
Event	Desflurane N = 1843	Isoflurane N = 626
Nausea	23%	17%
Respiratory Disorder (breath-holding)	16%	< 1%
Cough Increased	15%	< 1%
Vomiting	13%	10%
Apnoea	9%	0%
Laryngismus	8%	2%
Bradycardia	2%	1%
Conjunctival hyperaemia	2%	0%
Hypotension	2%	4%
Tachycardia	2%	1%
Headache	1%	< 1%
Hypertension	1%	1%
Nodal Arrhythmia	1%	0%
Pharyngitis	1%	< 1%
Arrhythmia	< 1%	< 1%
Asthma	< 1%	< 1%
Creatinine Phosphokinase increased	< 1%	< 1%
Dizziness	< 1%	< 1%
Increased Salivation	< 1%	0%
Nausea and Vomiting	< 1%	1%

As with other agents of this type, desflurane anaesthesia has been shown to trigger a skeletal muscle hypermetabolic state leading to high oxygen demand and the clinical syndrome known as malignant hyperthermia (see section 4.4). The syndrome includes non-specific features such as hypercapnia, muscle rigidity, tachycardia, tachypnoea, cyanosis, arrhythmias and unstable blood pressure and an increase in overall metabolism may be reflected in an elevated temperature. Some of these non-specific signs may also appear during light anaesthesia: acute hypoxia, hypercapnia and hypervolaemia. Renal failure may appear later.

¹ Anesthesiology 1995:83(5): 1125-1129.

Reporting of suspected adverse reactions

Reporting suspected adverse reactions after authorisation of the medicine is important. It allows continuing monitoring of the benefit/risk balance of the medicine. Healthcare professionals are asked to report any suspected adverse reactions https://nzphv.otago.ac.nz/reporting/

4.9 Overdose

Human experience There is no experience of overdosage in humans.

Symptoms and treatment of overdosage

The symptoms of overdosage of **Suprane** are anticipated to be similar to those of other volatile agents with a deepening of anaesthesia, cardiac and/or respiratory depression in spontaneous breathing patients, and cardiac depression in ventilated patients in whom hypercapnia and hypoxia may occur only at a late stage.

In the event of overdosage or what may appear to be overdosage, the following actions should be taken: stop **Suprane**, establish a clear airway and initiate assisted or controlled ventilation with pure oxygen and support and maintain adequate haemodynamics.

For advice on the management of overdose please contact the National Poisons Centre on phone number: 0800 764 766 [0800 POISON] in New Zealand (or 131126 in Australia).

	Halogenated hydrocarbons
ATC code	N01AB07.

Mechanism of action

Desflurane is one of a family of halogenated methylethylethers which is administered by inhalation producing a dose-related, reversible loss of consciousness and of pain sensations, suppression of voluntary motor activity, modification of autonomic reflexes and sedation of respiration and the cardiovascular system. Other members of the series include enflurane and its structural isomer isoflurane which are halogenated with chlorine as well as fluorine. Desflurane is halogenated exclusively with fluorine. Consistent with its high degree of fluorination, desflurane exhibits very low solubility in water with a corresponding low blood/gas partition coefficient. The low blood/gas partition coefficient of desflurane (0.42) is lower than that of other potent inhaled anaesthetics such as isoflurane (1.4) and even lower than that of nitrous oxide (0.46). Changes in the clinical effects of Suprane rapidly follow changes in the inspired concentration. These data explain the rapid washout with desflurane anaesthesia, but clinical studies have not shown a faster time to hospital discharge when desflurane was compared with related agents. Animal studies showed a more rapid induction and recovery from anaesthesia than for isoflurane, with a similar cardiorespiratory profile. There SUPRANE Data Sheet 31 July 2019 Page **13** of **19** Baxter Healthcare Ltd

were no signs of epileptogenic or other untoward effects of EEG, and adjuvant medicines produced no unanticipated or toxic EEG responses during anaesthesia with desflurane.

Studies in pigs bred to be susceptible to malignant hyperthermia (MH) indicated that desflurane is a potential trigger for MH.

The pharmacological effect is proportional to the inspired concentration of desflurane. The main adverse effects are extensions of the pharmacological action.

Active ingredient	Desflurane	
Chemical name	(±) 2-difluoromethyl-1,2,2,2-tetrafluoroethyl ether	
Chemical structure	F H F I I I F	
Molecular formula	$C_3H_2F_6O$	
CAS number	57041-67-5	
Molecular Weight	168.04	
Physiochemical characteristics	Boiling Point Polymorphism Specific gravity Vapour density Vapour pressure (mm Hg) Minimum Flammable Concentration:	22.8°C Desflurane does not exhibit polymorphism 1.4672g/mL (determined at 15°C) 3g/L at 1 atm (22°C) 20°C 669 22°C 731 23°C 764 24°C 798 26°C 869 19.75% (70% N ₂ O/30% O ₂) 17.8% (100% O ₂).
Solubility	Desflurane is not miscible with miscible with the common org methanol, acetone, ether, chlo acetonitrile, and hexane in all p	aqueous substances. It is anic solvents including proform, methylene chloride,

Clinical efficacy and safety

The safety and efficacy of desflurane have been established in large, multicentre clinical trials in adult outpatients (ASA I, II and III), in cardiovascular surgery (ASA II, III and IV) patients, in elderly (ASA II and III) patients and in paediatric (ASA I and II) patients.

Ambulatory surgery

Desflurane was compared to isoflurane in multicentre studies (21 sites) of 792 ASA physical status I, II or III patients aged 18 - 76 years (median 32 years). Desflurane with or without nitrous oxide or other anaesthetics was generally well tolerated. Patients receiving desflurane emerged significantly faster than those receiving isoflurane, and there were no differences in the incidence of nausea and vomiting.

Cardiovascular surgery

Desflurane was compared to isoflurane, sufentanil or fentanyl for the anaesthetic management of coronary artery bypass graft (CABG), abdominal aortic aneurysm, peripheral vascular and carotid endarterectomy surgery in 7 studies at 15 centres involving a total of 558 patients (ASA physical status II, III and IV).

Cardiac studies

The effects of desflurane in patients undergoing CABG surgery were investigated in three studies.

Using echocardiography in addition to Holter monitoring to detect myocardial ischaemia, one study compared desflurane with sufentanil in groups of 100 patients each. The opioid group received a small dose of thiopentone, and sufentanil, 5 - 10µg/kg followed by an infusion of 0.07µg/kg/min, and no halogenated anaesthetic. The desflurane group received no opioid for induction of anaesthesia, and after intravenous thiopentone had a rapid inhaled induction of anaesthesia with desflurane concentrations exceeding 10% end-tidal. The desflurane group had increases in heart rate (HR) and mean arterial pressure (MAP) during induction of anaesthesia and a 13% incidence of myocardial ischaemia during induction of anaesthesia which was greater than the zero incidence during induction in the sufentanil group. During the precardiopulmonary bypass period, more desflurane patients required cardiovascular adjuvants to control haemodynamics than the sufentanil patients. During maintenance of anaesthesia, the sufentanil group had myocardial ischaemia of greater duration and intensity than did the **Suprane** group. There were no differences in incidence of myocardial infarction or death between the two groups.

The second study compared desflurane with fentanyl in groups of 26 and 25 patients, respectively. The fentanyl group received 50μ g/kg and no halogenated inhaled anaesthetic. The desflurane group received fentanyl 10μ g/kg and a maximum desflurane end-tidal concentration of 6%. The groups did not differ in the incidence of electrocardiographic changes suggestive of ischaemia, myocardial infarction, or death.

In the third study, investigators compared desflurane with isoflurane in groups of 57 and 58 patients, respectively. Both groups were given up to $10\mu g/kg$ fentanyl during induction of anaesthesia. The mean end-tidal anaesthetic concentrations prior to coronary bypass were 6% desflurane or 0.9% isoflurane. Desflurane and isoflurane provided clinically acceptable anaesthesia prior to and after coronary bypass. A sub-analysis was performed for data collected at one of the study centres. At this centre desflurane was administered to 21 patients and 20 patients received isoflurane. Both groups were given fentanyl $10\mu g/kg$; during induction of anaesthesia the maximum end-tidal anaesthetic concentrations were 6% desflurane or 1.4% isoflurane. The groups had similar incidence of ischaemia (as detected by Holter monitoring), myocardial infarction, and death.

In the desflurane versus sufentanil study, investigators increased desflurane concentration rapidly to 10.2% end-tidal, without having administered any opioid, thereby increasing HR and MAP and observing a 13% incidence of myocardial ischaemia in their patients with coronary artery disease. These rapid increases in desflurane concentration without pre-treatment with an opioid, have been demonstrated to increase sympathetic activity, HR and MAP in volunteers. The other studies avoided these increases in HR and MAP by applying lower desflurane concentrations (less than 1

MAC), and by administering substantial doses of fentanyl (10 and $50\mu g/kg$) as part of the induction technique.

Peripheral vascular studies

Four randomised, open-label trials were conducted to assess the haemodynamic stability of patients administered desflurane versus isoflurane for maintenance of anaesthesia in peripheral vascular surgeries. These studies are summarised in the table below.

Summary of Doses in Peripheral Vascular Surgery Studies					
Type of Surgery		Desflurane/O ₂		lsoflurane/O₂	
	N	Mean End-tidal Concentrations (%)	N	Mean End-tidal Concentrations (%)	
Abdominal aorta	25	5.2	29	0.74	
Peripheral vascular	24	2.9*	24	0.43*	
Carotid endarterectomy	31	4.4	30	0.7	
	15	6.1	15	0.65	
*Desflurane and isoflurane administ	ered with 6	0% N ₂ O			

In all patients, the volatile anaesthetics were supplemented with fentanyl. Blood pressure and heart rate were controlled by changes in concentrations of the volatile anaesthetics or opioids and cardiovascular medicines, if necessary. No differences were found in cardiovascular outcome (death, myocardial infarction, ventricular tachycardia or fibrillation, heart failure) for desflurane and isoflurane in these studies.

Desflurane should not be used as the sole anaesthetic in patients with coronary artery disease or in patients where increases in the heart rate or blood pressure are undesirable (see section 4.4).

Geriatric surgery

Desflurane plus nitrous oxide was compared to isoflurane plus nitrous oxide in a multicentre study (6 sites) of 203 ASA physical status II or III elderly patients, aged 57 - 91 years (median 71 years). Heart rate and arterial blood pressure remained within 20% of pre-induction baseline values during administration of desflurane end-tidal concentrations of 0.5 - 7.7% (average 3.6%) with 50 - 60% nitrous oxide. Maintenance and recovery cardiovascular measurements did not differ from those during isoflurane plus nitrous oxide administration, nor did the postoperative incidence of nausea and vomiting. The most common cardiovascular adverse event was hypotension for both isoflurane (6%) as well as desflurane (8%).

Neurosurgery

Desflurane was administered to 56 patients aged 26 - 77 (median 48 years), ASA physical status II or III undergoing neurosurgical procedures for intracranial lesions. A further 59 patients are reported in the literature. All volatile anaesthetics may increase intracranial pressure in patients with space occupying lesions. In such patients, desflurane should be administered at 0.8 MAC or less in conjunction with a barbiturate or propofol induction and hyperventilation (hypocapnia) in the period before cranial decompression. Appropriate attention must be paid to maintain cerebral perfusion pressure. The use of a lower dose of desflurane and the administration of a barbiturate and mannitol would be predicted to lessen the effect of desflurane on CSFP.

Paediatric surgery

Desflurane was compared to halothane, with or without nitrous oxide, in 323 patients aged 2 weeks to 12 years (median 2 years), ASA physical status I or II.

Desflurane is not suitable for induction of anaesthesia in children and infants. Induction of anaesthesia with desflurane demonstrated an unacceptably high incidence of coughing (72%), breath-holding (68%), laryngospasm (50%), secretions (21%) and apnoea. The occurrence of oxyhaemoglobin desaturation was 26%. Premedication did not have an effect on tempering these upper airway responses to desflurane induction.

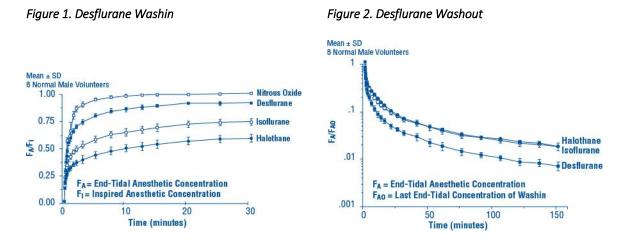

The concentration of desflurane required for maintenance of anaesthesia is age dependent (see section 4.2). Changes in blood pressure during maintenance of and recovery from anaesthesia were similar between desflurane $/N_2O/O_2$ and halothane $/N_2O/O_2$. Heart rate during maintenance of anaesthesia was approximately 10 beats/min faster with desflurane than with halothane. Patients were judged fit for discharge from post-anaesthesia care units within one hour with both desflurane and halothane. There were no differences in the incidence of nausea and vomiting between desflurane and halothane.

Obstetric surgery

Desflurane was studied in a total of 133 ASA physical status I or II patients for analgesia during vaginal delivery, anaesthesia for Caesarean section and elective D&C for termination of pregnancy. Due to the limited number of patients studied, the safety of desflurane has not been established for use in obstetric procedures (see section 4.6 Pregnancy).

5.2 Pharmacokinetic properties

As predicted from its physiochemical profile, pharmacokinetic studies in animals as in man indicate that desflurane washes into the body more rapidly than other volatile anaesthetics (see Figure 1). It also washes out of the body more rapidly allowing quick recovery and flexibility in adjustment of the depth of anaesthesia (see figure 2). Desflurane is eliminated via the lungs, undergoing only minimal metabolism (0.02%).

Minimum Alveolar Concentration (MAC) decreases with increasing age. A reduction of dosage is recommended in hypovolaemic, hypotensive and debilitated patients, as discussed under section 4.4.

5.3 Preclinical safety data

Genotoxicity

Desflurane did not show evidence of genotoxicity in assays for gene mutations and chromosomal damage.

Carcinogenicity

No studies on the potential carcinogenic activity of desflurane have been conducted.

Preclinical Safety Data

The potential for desflurane to sensitise the myocardium to exogenously administered adrenaline is similar to that of isoflurane in swine. Desflurane appears to produce coronary vasodilation at arteriolar level in selected animal models, in a similar fashion to that of isoflurane. In an animal model simulating coronary artery disease with conscious, chronically instrumented dogs, desflurane does not appear to divert blood from collateral dependent myocardium to normally perfused areas (coronary steal). Clinical studies to date evaluating myocardial ischaemia, infarction and death as outcome parameters have not established that the coronary arteriolar property of desflurane is associated with coronary steal or myocardial ischaemia in patients with coronary artery disease.

6 PHARMACEUTICAL PARTICULARS

6.1 List of excipients

There are no excipients in this formulation.

6.2 Incompatibilities

No data available.

6.3 Shelf life

36 months. The expiry date can be found on the packaging.

6.4 Special precautions for storage

Store at or below 30°C.

Store bottle in an upright position. To avoid leakage, apply bottle cap firmly to valve, but not too tightly. **Suprane** must be kept in the original container until immediately prior to use.

6.5 Nature and contents of container

Suprane is available in an aluminium bottle containing 240mL desflurane.

6.6 Special precautions for disposal and other handling

Replace cap after use.

Any unused medicine or waste material should be disposed of in accordance with local requirements.

Suprane should only be administered by persons trained in the administration of general anaesthesia, using a vapourizer designed and designated for use with **Suprane** (see section 4.4).
